

ITCM Kernel: Hypergeometric Factor ${}_2F_1(a_1, b_1; c_1; \xi)$

Parameters: $a_1 = (\mu + \nu)/2 + 1$, $b_1 = (\mu - \nu)/2 + 1$, $c_1 = \mu + 1$. The universal Euler exponent $c_1 - a_1 - b_1 = -1$ produces a simple pole at $\xi = 1$ in all three cases. As $\mu \neq \nu$ increases (Hankel-order asymmetry), the kernel grows faster near $\xi = 1$, strengthening the Green's function singularity that drives confinement.
